

The background features a complex network of blue lines and arrows. Some lines are solid and straight, while others are dashed and curved. Arrows indicate a flow or direction, often following the paths of the dashed lines. The overall aesthetic is technical and dynamic.

Adsorption Fundamentals

- The last lecture looked at Adsorption as an observation of typical results
- Today we will look at it from more of a viewpoint of fundamental principles
 - *Did someone say “Material Balances”?*

- The concentration of solute in the solution, c , is changing because the solute is being adsorbed onto the surface of the adsorbent solid
- The change in superficial velocity is small for a dilute solution and we will treat it as a constant, u_0
- ϵ is the external void fraction (i.e. How much open space exists around the particles)
- $(1 - \epsilon)$ is the fraction of space taken up by the adsorbent particles

Adsorption Fundamentals

- The change in the amount of solute per unit cross-sectional area is:

$$u_0 c - u_0 (c + dc) = -u_0 dc$$

what goes in the control volume – what leaves the control volume = change in amount in control volume

- The change in the amount of solute results from two different causes:

1) The change in the fluid concentration

$$\epsilon dl \frac{\partial c}{\partial t}$$

ϵdl is the volume of fluid in the control volume per unit cross-sectional area

$\frac{\partial c}{\partial t}$ is the change in concentration (mass/volume) with respect to time

2) The change in surface adsorption

$$(1 - \epsilon) dl \rho_p \frac{\partial w}{\partial t}$$

Adsorption Fundamentals

- The change in surface adsorption

$$(1 - \epsilon) dl \rho_p \frac{\partial w}{\partial t}$$

- $(1 - \epsilon) dl$ is the volume occupied by particles in the control volume per unit cross-sectional area
- ρ_p is the mass of particles per unit volume
- $(1 - \epsilon) dl \rho_p$ is the mass of particles in the control volume per unit cross-sectional area
- $\frac{\partial w}{\partial t}$ is the change with respect to time of the $\frac{\text{mass of solute adsorbed}}{\text{mass of adsorbent particles}}$
- The two causes added to one another must equal the change in the amount of solute in the control

volume per unit cross-sectional area, therefore we arrive at this partial differential equation:

$$\epsilon dl \frac{\partial c}{\partial t} + (1 - \epsilon) dl \rho_p \frac{\partial w}{\partial t} = -u_0 dc$$

$$\epsilon \frac{\partial c}{\partial t} + (1 - \epsilon) \rho_p \frac{\partial w}{\partial t} = -u_0 \frac{\partial c}{\partial l}$$

Mass Transfer to Adsorbent Particles

Three Steps:

- 1) Diffusion through film layer around the particle
- 2) Diffusion through pores into internal surfaces
- 3) Actual adsorption step
 - Practically instantaneous relative to steps 1) and 2)

This can be modeled as:

$$(1 - \epsilon) \rho_p \frac{\partial w}{\partial t} = K_c a (c - c^*)$$

a is the external surface area of the particles

c^* is the concentration value in equilibrium with w

- Obtained via the isotherm

$$\frac{1}{K_c} = \frac{1}{k_{c_{ext}}} + \frac{1}{k_{c_{int}}} = \frac{1}{\text{Film Resistance}} + \frac{1}{\text{Pore Resistance}}$$

- These equations are not generally solvable, but there are special cases that can be worked out

Regeneration

- If the particles and the product can withstand high temperatures, then you can use heat to release the product from the adsorbent

- At higher temperature the equilibrium shifts and the adsorbent releases the solute
- Use a back flow of steam or air (if the materials are all non-flammable) or N_2
- Regeneration is stopped soon after the temperature front reaches the feed entrance
 - A significant amount of adsorbed material remains which means breakthrough time is reduced
 - Exit end is almost fully regenerated so that high percentage removal of solute is still possible
 - Balance of energy cost per cycle versus length of cycle

This problem deals with some experiments performed in Elroy Hutch's laboratory on adsorption of n-hexanol from air in a 10 cm long carbon-filled bed. Measured concentration profiles are shown in Fig. 1 for various times after the initial time $t = 0$, with $x =$ distance along bed.

Details of the experiment are as follows:

$u_0 =$ superficial gas velocity = 72 cm / s
 $c_0 =$ 250 ppm hexanol (ppm = mole fraction $\times 10^6$)
 $T_0 = 50^\circ\text{C}$
 $P = 690$ mm Hg
 $\rho_{\text{bed}} = 0.45$ g carbon / cm^3 bed volume

You may assume that $c(L,t) = 0$ for $t \leq 2$ h and $c(L,t) = c_0$ for $t \geq 9$ h.

- Prepare in either graphical or numerical form a representation of the breakthrough curve.
- Calculate the saturation capacity of the carbon and the fraction of the bed used (in terms of equivalent bed length) at the breakpoint if this is defined according to the criterion $c(L,t_b) = 0.10 c_0$.
- Assuming that the unused length of bed is independent of total bed length, estimate the break-point time for a 20 cm long bed.

7	0.90	0.10	0.06
8	0.98	0.02	0.01
9	1	0	

Handwritten note: A bracket groups the values 2, 0.99, 0.94, 0.80, 0.50, 0.20, 0.06, and 0.01, with the text "upto breakpoint" written next to it.

(c)

$$t_{b2}/t_{b1} = \frac{L_2 * \left(1 - \frac{LUB}{L_2}\right)}{L_1 * \left(1 - \frac{LUB}{L_1}\right)}$$

This problem deals with some experiments performed in Elroy Hutch's laboratory on adsorption of water from air in a bed filled with silica gel (length $L = 60$ cm). Measured concentration profiles are shown in Fig. 4 for various times after the initial time $t = 0$, with $x =$ distance along bed. You may assume that $c(L,t) = 0$ for $t \leq 2$ h. Details of the experiment are as follows:

$$u_o = \text{superficial gas velocity} = 13.1 \text{ cm/s};$$

$$y_o = \text{water mole fraction in entering gas} = 5210 \times 10^{-6};$$

$$T = 20^\circ\text{C};$$

$$P = 3.0 \text{ atm};$$

$$\rho_{\text{bed}} = 0.30 \text{ g silica gel/cm}^3 \text{ bed volume}$$

The break-point time t_b is defined by the criterion $c(L,t_b) = 0.10 c_o$.

Elroy abandoned the experiment after 5 hours (to go buy some bananas to eat). Thus, insufficient data exist to determine the saturation capacity of the bed by time integration. Figure 5 will allow you to determine W_{sat} by alternate means.

- (10 points) What is the saturation capacity of the bed W_{sat} in g water/g silica gel?
- (30 points) What is the unused capacity of the silica gel (in terms of equivalent bed length) at the break-point?
- (10 points) Estimate the break-point time for a longer bed length of 100 cm, all other conditions being equal.

University at Buffalo

Department of Chemical
and Biological Engineering
School of Engineering and Applied Sciences

This problem deals with some experiments performed in Elroy Hutch's laboratory on adsorption of n-hexanol from air in a 10 cm long carbon-filled bed. Measured concentration profiles are shown in Fig. 1 for various times after the initial time $t = 0$, with x = distance along bed.

Details of the experiment are as follows:

u_0 = superficial gas velocity = 72 cm / s
 c_0 = 250 ppm hexanol (ppm = mole fraction $\times 10^6$)
 $T^0 = 50^\circ\text{C}$
 $P = 690$ mm Hg
 $\rho_{\text{bed}} = 0.45$ g carbon / cm^3 bed volume

You may assume that $c(L, t) = 0$ for $t \leq 2$ h and $c(L, t) = c_0$ for $t \geq 9$ h.

- Prepare in either graphical or numerical form a representation of the breakthrough curve.
- Calculate the saturation capacity of the carbon and the fraction of the bed used (in terms of equivalent bed length) at the breakpoint if this is defined according to the criterion $c(L, t_b) = 0.10 c_0$.
- Assuming that the unused length of bed is independent of total bed length, estimate the break-point time for a 20 cm long bed.

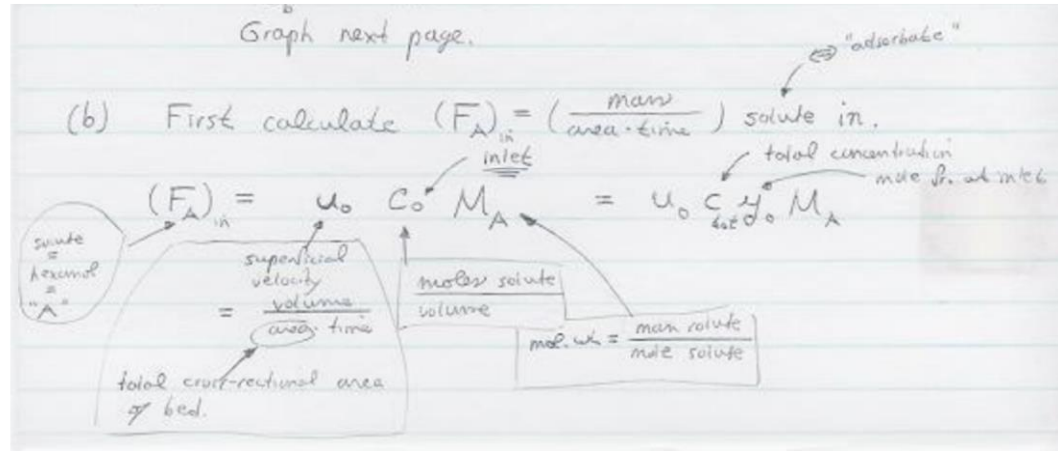

(a) Breakthrough curve is $c(L, t)/c_0$ plotted as function of time. From graph provided (Fig.1), construct table.

t (h)	$c(L, t)/c_0$
0	0
2	0
3	0.02
4	0.10
5	0.30
6	0.70
7	0.90
8	0.98
9	1
(all later times)	1

Note: breakpoint (time @ which $c(L, t)/c_0 = 0.10$) is $t_b = 4$ h.

$$w(t) = \frac{\int_0^t F_{A \text{ in}} \left(1 - \frac{c}{c_0}\right) dt}{L \rho_{bed}}$$

$$\frac{W_b}{W_{sat}} = \text{fraction of bed utilized}$$

$$= \left(72 \frac{\text{cm}}{\text{s}}\right) \left(\frac{1 \text{ mol}}{22400 \text{ cm}^3}\right) \times \frac{273 \text{ K}}{323 \text{ K}} \times \frac{590 \text{ mmHg}}{760 \text{ mmHg}}$$

↑ mole density @ 273 K and 1 atm ↑ correct for 50°C ↑ correct for 680 mmHg

$$\times \left(250 \times 10^{-6}\right) \left(102.18 \frac{\text{g hexanol}}{\text{mol hexanol}}\right)$$

mole fraction hexanol = $\frac{\text{mole hexanol}}{\text{mole}}$ mol. wt.

$$= \left(6.301 \times 10^{-5} \frac{\text{g}}{\text{cm}^2 \cdot \text{s}} \text{ hexanol}\right) \left(\frac{3600 \text{ s}}{\text{h}}\right)$$

$(F_A)_{in} = 0.227 \frac{\text{g solute}}{\text{cm}^2 \cdot \text{h}}$

For review, $(F_A)_{out} = u_0 c M_A = (u_0 c_0 M_A) \left(\frac{c}{c_0}\right) = (F_A)_{in} \frac{c}{c_0}$

Solute accumulated in bed in time interval $(t, t+dt)$ is $[(F_A)_{in} - (F_A)_{out}] dt = (F_A)_{in} \left(1 - \frac{c}{c_0}\right) dt$. ← (mass/area)

Total solute accumulated by bed from time zero to time t is $(F_A)_{in} \int_0^t \left(1 - \frac{c}{c_0}\right) dt$. Note: what we here call $(F_A)_{in}$ book calls F_A .

$$\left(\frac{\text{mass}}{\text{area}}\right) \text{ adsorbed upto } t_b = (F_A)_{in} \int_0^{t_b} \left(1 - \frac{c}{c_0}\right) dt$$

$$\left(\frac{\text{mass}}{\text{area}}\right) \text{ adsorbed upto } t \rightarrow \infty = (F_A)_{in} \int_0^{\infty} \left(1 - \frac{c}{c_0}\right) dt = \text{capacity of bed}$$

Prepare table for numerical integration (next page). can stop at 9h because $1 - \frac{c}{c_0}$ is essentially zero for all later times.

(4h)

$$\epsilon(h) = 1 - \frac{c(L, t)}{c_0} \quad \text{contribution to integral } \int_0^{\epsilon} (1 - \frac{c}{c_0}) dt \quad (4)$$

0	1	>	2	} upto breakpoint
2	1	>	0.99	
3	0.98	>	0.94	
4	0.90	>	0.80	
5	0.70	>	0.50	
6	0.30	>	0.20	
7	0.10	>	0.06	
8	0.02	>	0.01	
9	0	>		

$$\int_0^{\epsilon_b} (1 - \frac{c}{c_0}) dt = (2 + 0.99 + 0.94)h = 3.93 h$$

$$\int_0^{\infty} (1 - \frac{c}{c_0}) dt = (3.93 + 0.80 + 0.50 + 0.20 + 0.06 + 0.01)h = 5.50 h$$

$$\left(\frac{\text{mass}}{\text{area}}\right) \text{ adsorbed upto } \epsilon_b = (0.227 \frac{\text{g}}{\text{cm}^2 \cdot \text{h}})(3.93 h) \text{ solute}$$

$$\left(\frac{\text{mass}}{\text{area}}\right) \text{ adsorbed upto } \epsilon_{\infty} = (0.227 \frac{\text{g}}{\text{cm}^2 \cdot \text{h}})(5.50 h) \text{ solute}$$

Capacity generally expressed in terms of W ($\frac{\text{mass adsorbed}}{\text{mass adsorbent}}$).

$$\text{Know } \frac{\text{mass bed}}{\text{area}} = \frac{\text{vol. bed}}{\text{area}} \cdot \frac{\text{mass bed}}{\text{volume}} = L \rho_{\text{bed}}$$

$$= (10 \text{ cm}) \left(\frac{0.45 \text{ g}}{\text{cm}^3} \right) = 4.5 \frac{\text{g carbon}}{\text{cm}^2}$$

† Use trapezoid rule, $\int_a^b f(x) dx \approx \frac{b-a}{2} [f(a) + f(b)]$, for each interval.

$$W_b = \frac{(0.227 \frac{\text{g}}{\text{cm}^2 \cdot \text{h}})(3.93 h) \text{ solute}}{4.5 \frac{\text{g}}{\text{cm}^2} \text{ carbon}} = 0.198 \frac{\text{g solute}}{\text{g carbon}} \quad \text{adsorbed upto breakpoint}$$

$$W_{\text{sat}} = \frac{(0.227 \frac{\text{g}}{\text{cm}^2 \cdot \text{h}})(5.50 h) \text{ solute}}{4.5 \frac{\text{g}}{\text{cm}^2} \text{ carbon}} = 0.277 \frac{\text{g solute}}{\text{g carbon}} \quad \text{bed completely saturated}$$

saturation capacity of the carbon

fr. bed capacity used at ϵ_b

Fraction of bed capacity utilized at breakpoint

$$= W_b / W_{\text{sat}} = \frac{0.198}{0.277} = 0.715$$

$$\text{for } 10 \text{ cm bed. Used length} = (0.715)(10 \text{ cm}) = 7.15 \text{ cm}$$

$$\text{Unused length} = 10 - 7.15 = 2.85 \text{ cm}$$

equivalent unused length

equivalent used length

(c)

$$t_{b2}/t_{b1} = \frac{L_2 * \left(1 - \frac{LUB}{L_2}\right)}{L_1 * \left(1 - \frac{LUB}{L_1}\right)}$$

$$t_{b1}=4h; \quad L_2 =20cm; \quad L_1=10cm; \quad LUB=2.85cm$$

$$t_{b2}=9.6h$$

This problem deals with some experiments performed in Elroy Hutch's laboratory on adsorption of water from air in a bed filled with silica gel (length $L = 60$ cm). Measured concentration profiles are shown in Fig. 4 for various times after the initial time $t = 0$, with $x =$ distance along bed. You may assume that $c(L, t) = 0$ for $t \leq 2$ h. Details of the experiment are as follows:

$$u_o = \text{superficial gas velocity} = 13.1 \text{ cm/s};$$

$$y_o = \text{water mole fraction in entering gas} = 5210 \times 10^{-6};$$

$$T = 20^\circ\text{C};$$

$$P = 3.0 \text{ atm};$$

$$\rho_{\text{bed}} = 0.30 \text{ g silica gel/cm}^3 \text{ bed volume}$$

The break-point time t_b is defined by the criterion $c(L, t_b) = 0.10 c_o$.

Elroy abandoned the experiment after 5 hours (to go buy some bananas to eat). Thus, insufficient data exist to determine the saturation capacity of the bed by time integration. Figure 5 will allow you to determine W_{sat} by alternate means.

- (10 points) What is the saturation capacity of the bed W_{sat} in g water/g silica gel?
- (30 points) What is the unused capacity of the silica gel (in terms of equivalent bed length) at the break-point?
- (10 points) Estimate the break-point time for a longer bed length of 100 cm, all other conditions being equal.

Data: vapor pressure of water

T(°C)	$P_{\text{H}_2\text{O}}^{\text{sat}}$ (mm Hg)
20	19.8
30	31.8
40	55.3

Figure 24-3 Adsorption isotherms for water in air at 20 to 50°C.

(a) Incoming air: $P_{H_2O} = y_{H_2O} P$

$$= (5210 \cdot 10^{-6}) \left(3 \text{ atm} \times \frac{760 \text{ mmHg}}{1 \text{ atm}} \right)$$

$$= 11.88 \text{ mmHg}$$

at 0°C \rightarrow $P_{H_2O}^{sat} = 19.8 \text{ mmHg}$. Then

$$W_R = (100\%) \frac{P_{H_2O}}{P_{H_2O}^{sat}} = (100\%) \frac{11.88}{19.8} = 60.0\%$$

From Fig. 5, $W_{sat} = \frac{35.2 \text{ lb } H_2O}{100 \text{ lb silica gel}} = \boxed{0.352 \frac{\text{g } H_2O}{\text{g silica gel}}}$

$$w(t) = \frac{\int_0^t F_{A \text{ in}} \left(1 - \frac{c}{c_0}\right) dt}{L \rho_{bed}}$$

$$\frac{W_b}{W_{sat}} = \text{fraction of bed utilized}$$

(b) Solute in: W_{sat}

$$\begin{aligned}
 (F_A)_{in} &= \left(\frac{\text{mass}}{\text{area} \cdot \text{time}}\right) \text{ solute in } c_0 \\
 &= U_0 \cdot C_{tot} \cdot M_A \\
 &= (13.1 \text{ cm/s}) \left[\frac{(3 \times 10^{13} \text{ Pa})}{(8.314 \frac{\text{J}}{\text{mol} \cdot \text{K}})(293.15 \text{ K})} \times \frac{1 \text{ m}^3}{10^6 \text{ cm}^3} \right] \left(\frac{5210}{10^6}\right) \\
 &\rightarrow \times \frac{18.015 \text{ g solute}}{\text{mol solute}} \times \frac{3600 \text{ s}}{1 \text{ h}} \\
 &= 0.552 \frac{\text{g solute}}{\text{cm}^2 \cdot \text{h}}
 \end{aligned}$$

Read off value of $c(L, t)$ from graph. Prepare table. Break-point time t_b is time at which $c(L, t_b) = 0.10 c_0$, so $t_b = 5 \text{ h}$.

$t \text{ (h)}$	$\frac{c(L, t)}{c_0}$	$1 - \frac{c(L, t)}{c_0}$	Contrib. to integral $\int_0^t (1 - \frac{c}{c_0}) dt' \text{ (h)}$
0	0	1	2.000
2	0	1	0.995
3	0.01	0.99	0.975
4	0.04	0.96	0.930
$t_b \rightarrow 5$	0.10	0.90	4.900

So: $\int_0^{t_b} [1 - \frac{c(L, t)}{c_0}] dt = 4.900 \text{ h}$,
 and $(\frac{\text{mass solute}}{\text{area}})$ adsorbed upto $t_b = (F_A)_{in} (4.900 \text{ h})$
 To get capacity in mass solute adsorbed/mass silica gel, use the fact that

$$\begin{aligned}
 \left(\frac{\text{mass silica gel}}{\text{area}}\right) &= \frac{\text{bed vol.} \cdot \text{mass silica gel}}{\text{bed area} \cdot \text{bed vol.}} \\
 &= L \rho_{bed} = (60 \text{ cm})(0.30 \frac{\text{g silica gel}}{\text{cm}^3}) \\
 &= 18.0 \frac{\text{g silica gel}}{\text{cm}^2}
 \end{aligned}$$

Then $W_b = \frac{\text{mass adsorbed upto } t_b}{\text{mass silica gel}}$

* Use trapezoid rule, $\int_a^b f(x) dx \approx \frac{b-a}{2} [f(a) + f(b)]$, for each interval

$$\begin{aligned}
 &= \frac{\text{mass adsorbed upto } t_b / \text{area}}{\text{mass silica gel / area}} \\
 W_b &= \frac{(F_A)_{in} (4.900 \text{ h})}{(L P_{bed})} = \frac{(0.552 \frac{\text{g solute}}{\text{cm}^2 \cdot \text{h}})(4.900 \text{ h})}{10.0 \frac{\text{g silica gel}}{\text{cm}^2}} \\
 &= 0.150 \frac{\text{g solute}}{\text{g silica gel}}
 \end{aligned}$$

Fraction of bed capacity used at break-point

$$= W_b / W_{sat} = 0.150 / 0.352 = 0.426$$

for 60 cm bed. Used length = $(0.426)(60 \text{ cm})$
= 25.6 cm

Unused length = $(60 - 25.6) \text{ cm} = 34.4 \text{ cm}$

Unused capacity of bed (in terms of equivalent bed length) at break-point is $L_{unused} = 34.4 \text{ cm}$

(c)

$$t_{b2}/t_{b1} = \frac{L_2 * \left(1 - \frac{LUB}{L_2}\right)}{L_1 * \left(1 - \frac{LUB}{L_1}\right)}$$

$$t_{b1}=5\text{h}; \quad L_2 =100\text{cm}; \quad L_1=60\text{cm}; \quad LUB=34.4\text{cm}$$

$$t_{b2}= 12.8 \text{ h}$$
