Introduction to Plasma Processing

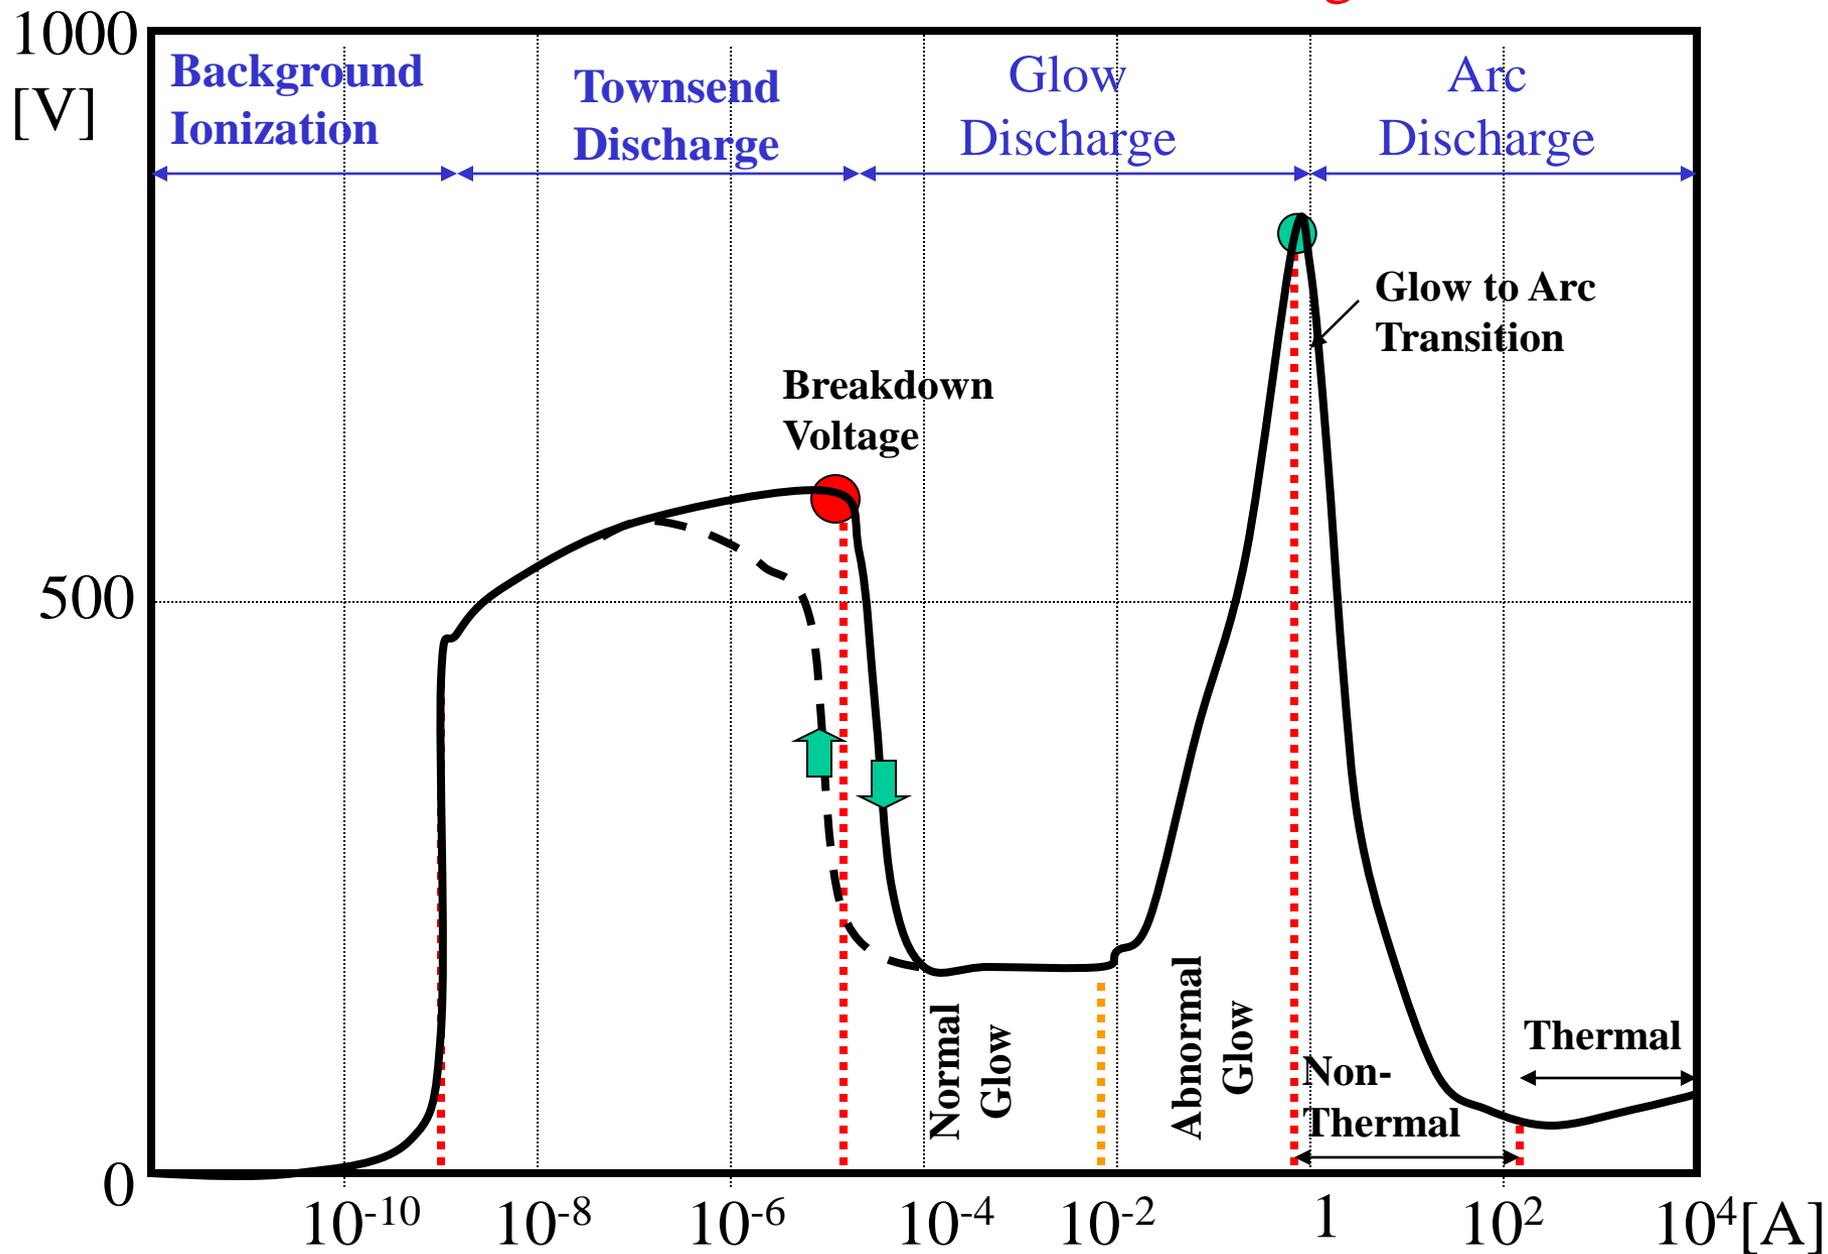

DC Discharge I

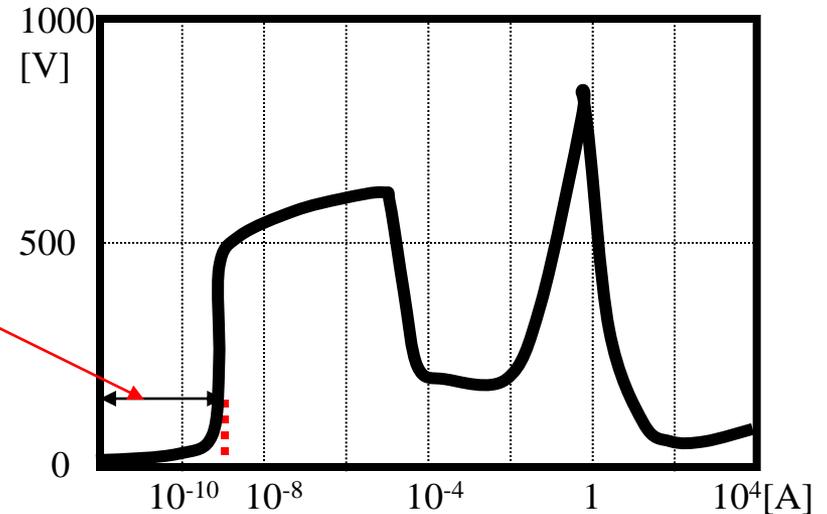

October 26, 2011

V-I Characteristic of DC Discharges

Background Ionization

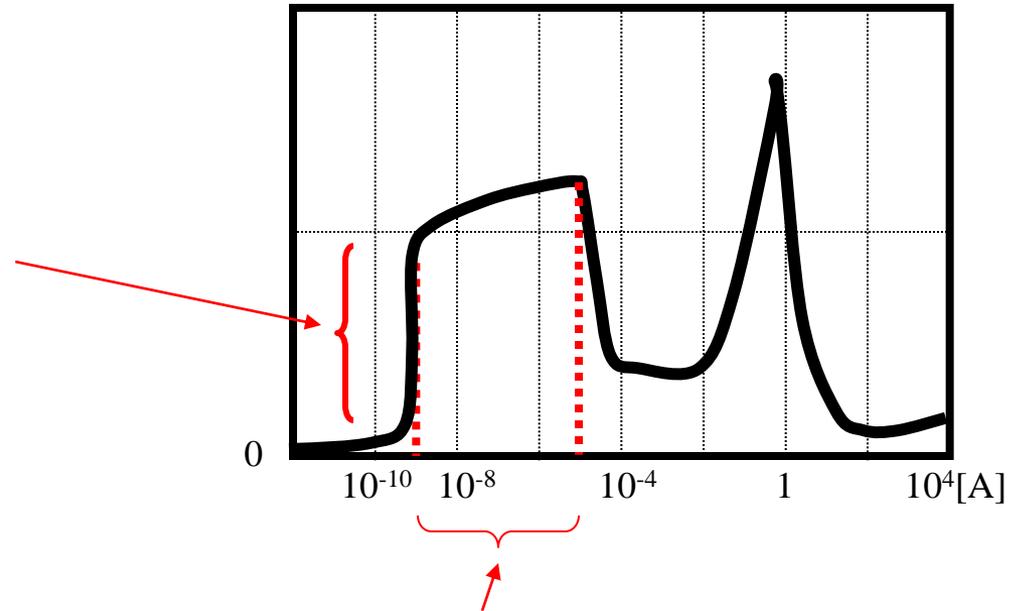

$$e \times d \times E = \frac{1}{2} m_e v_e^2 < \chi_{s, \min}$$

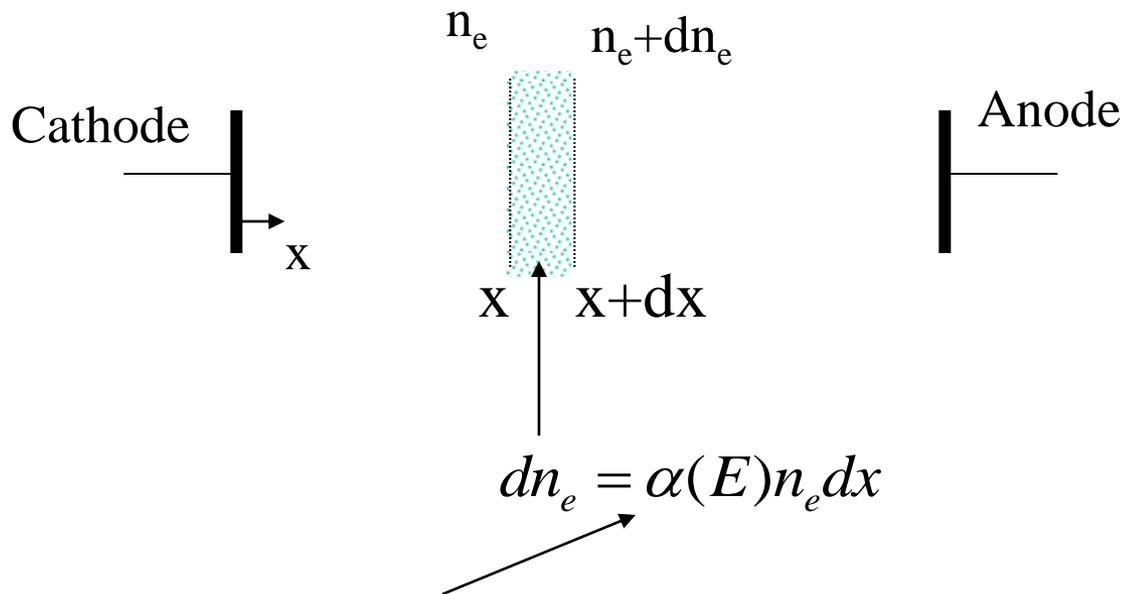

- e and A+ are generated by cosmic rays and other forms of background radiation
- No excitation take place
- Absolutely dark
- Non self sustaining discharge

-Collection of all electrons and ions that are produced by external radiation.

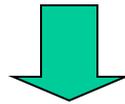

- A dark current discharge emits very little light

Electrons pick up sufficient energy in a mean free path to make ionizing collisions with neutrals. ($e\lambda_e E > \chi_i$)

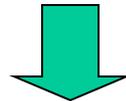

Ionization Coefficient (probable # of ionizing collision per meter)

Assuming E is constant
No Space Charge

$$n_e = n_{e0} e^{\alpha x}$$

$$j_e = j_{e0} e^{\alpha x}$$

First Townsend Coefficient (α)

λ Mean Free Path \rightarrow $1/\lambda$ is number mean free path per unit length.

λ_x Mean free path that meets the minimum requirement for ionization.

$f(\lambda_x) = e^{-\frac{\lambda_x}{\lambda}}$ Fraction of λ_x among all the λ .

$\alpha = \frac{1}{\lambda} e^{-\frac{\lambda_x}{\lambda}}$ Number of λ_x that lead to ionization

$$\lambda = \frac{A}{p}$$

$$\lambda_x = \frac{\text{const}}{E}$$

Depends on T_e
and Type of Gas

$$\alpha = \frac{p}{A} \exp\left(\left(\frac{-\text{const}}{E}\right) \div \left(\frac{A}{p}\right)\right)$$

First Townsend Coefficient (α)

$$\frac{\alpha}{p} = C_1 \times e^{\left(\frac{-C_2}{P}\right)}$$

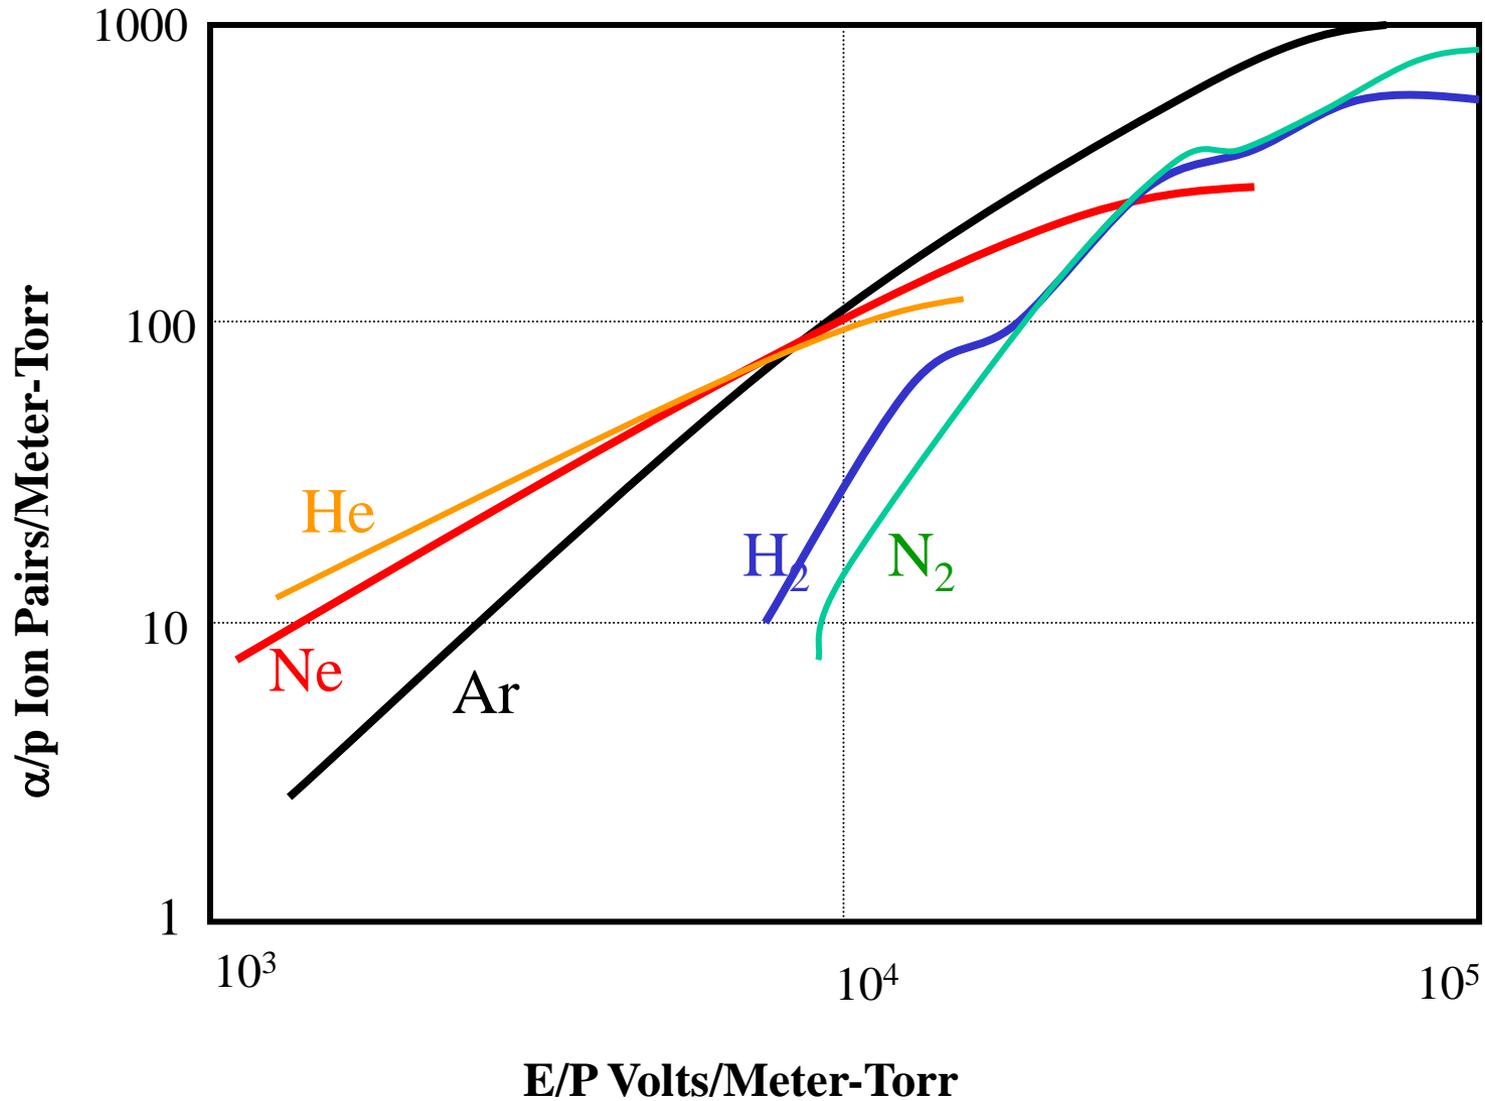

$$C_1 = \frac{1}{A}$$

$$C_2 = AV_i$$

Effective Ionization Potential

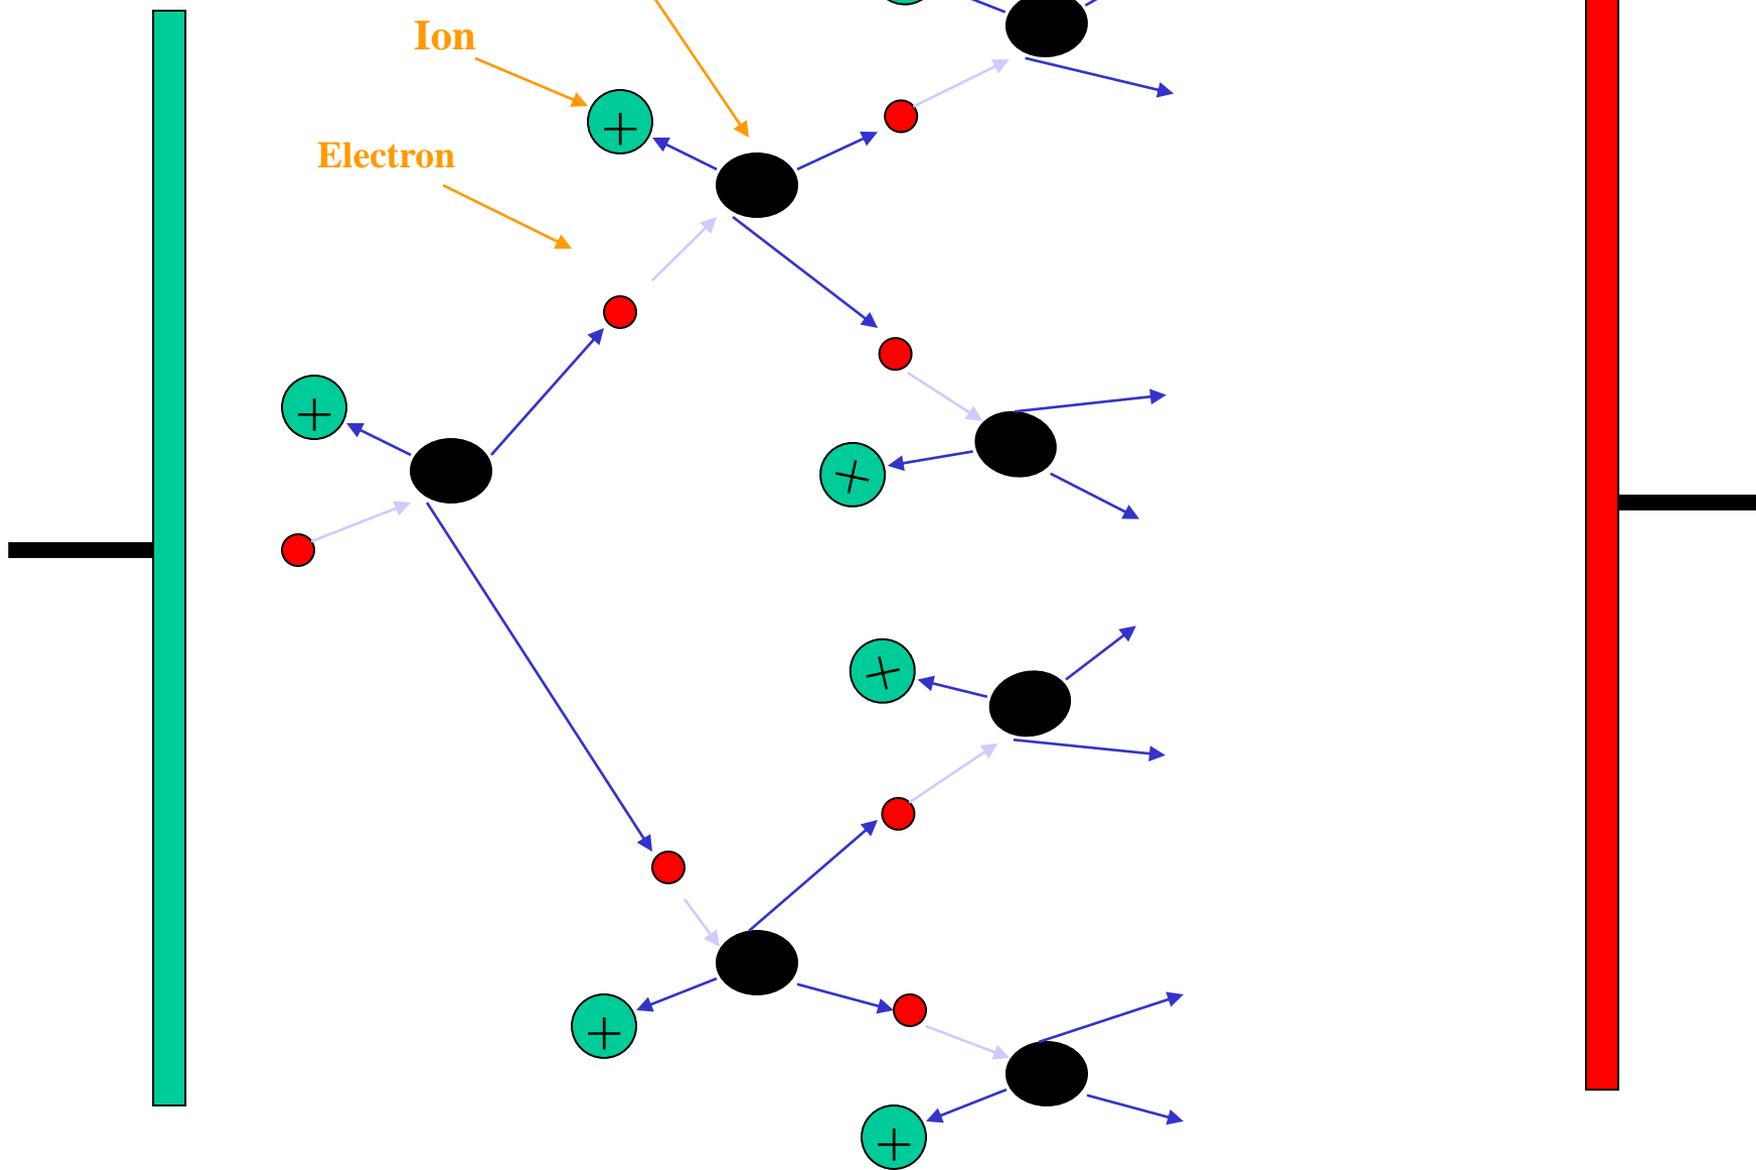

Gas	C_1 [ion pair/m-Torr]	C_2 V/m-Torr
Ar	1200	20 000
Air	1220	36 500
CO ₂	2000*	46 600
H ₂	1060	35 000
HCl	2500*	38 000
He	182	5 000
Hg	2000	37 000
H ₂ O	1290*	28 900
Kr	1450	22 000
N ₂	1060	34 200
Ne	400	10 000
Xe	2220	31 000

First Townsend Coefficient (α)

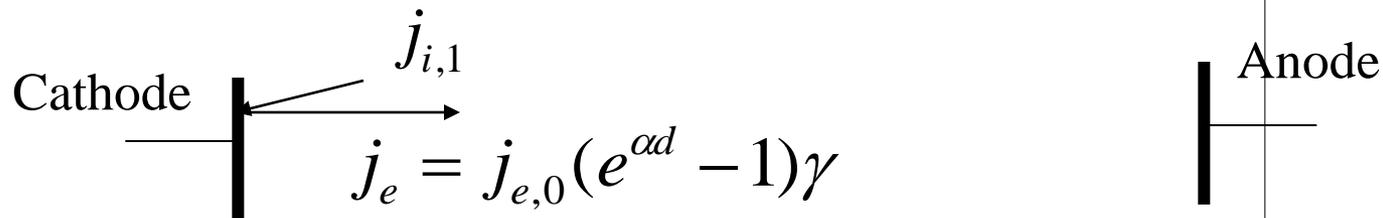

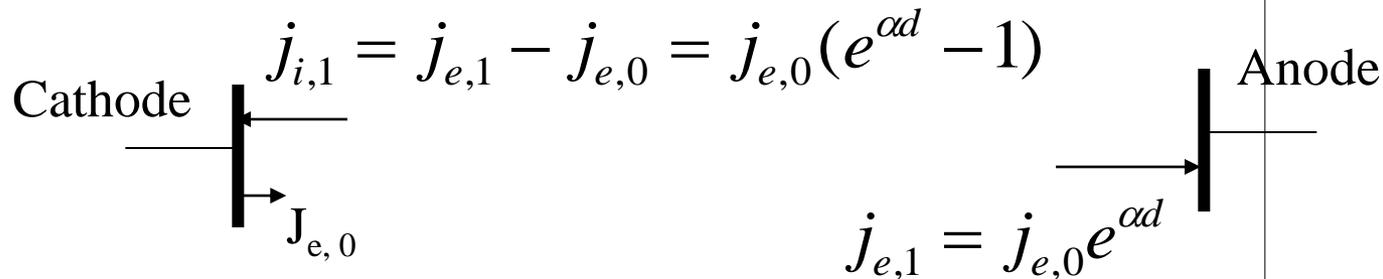

Cathode

Anode

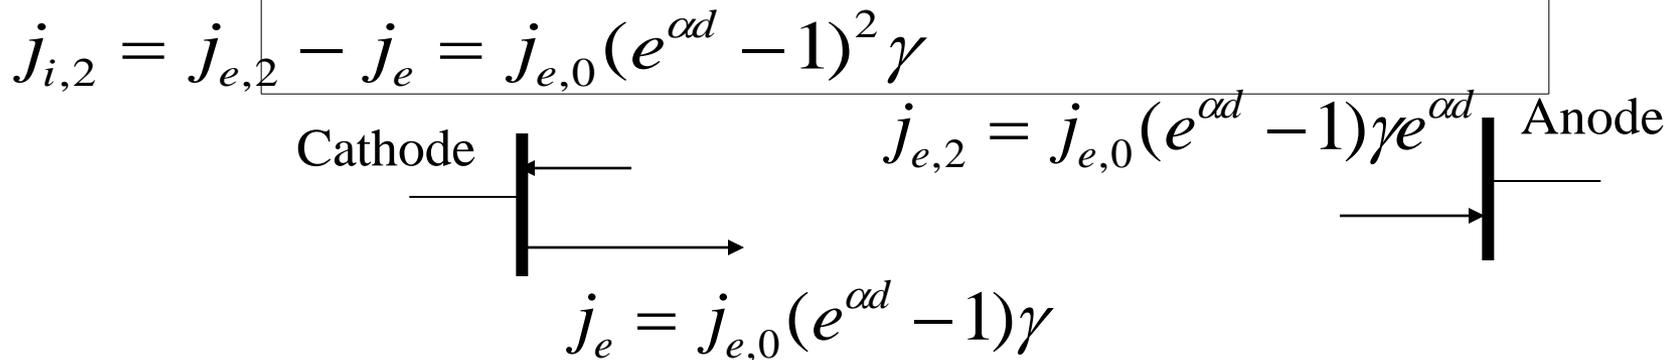

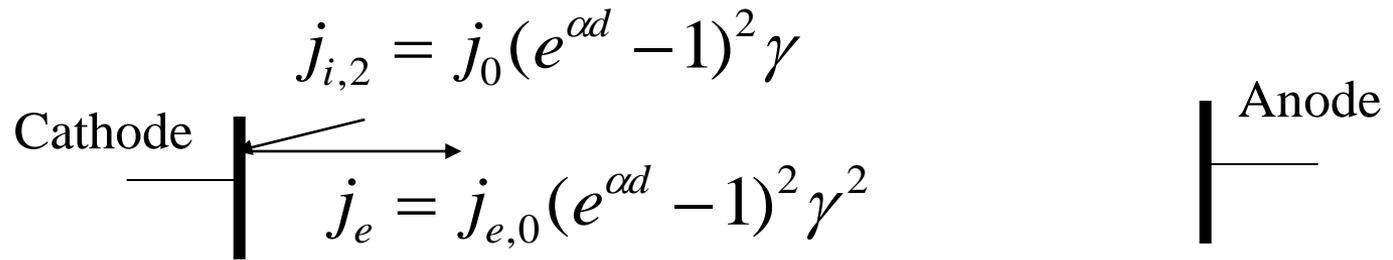

1st generation

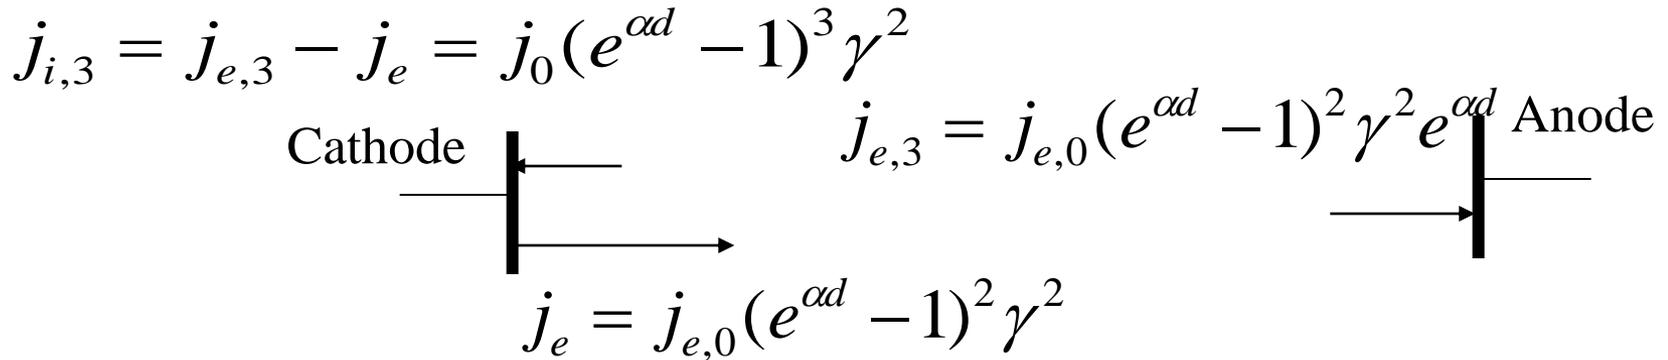

2nd Generation

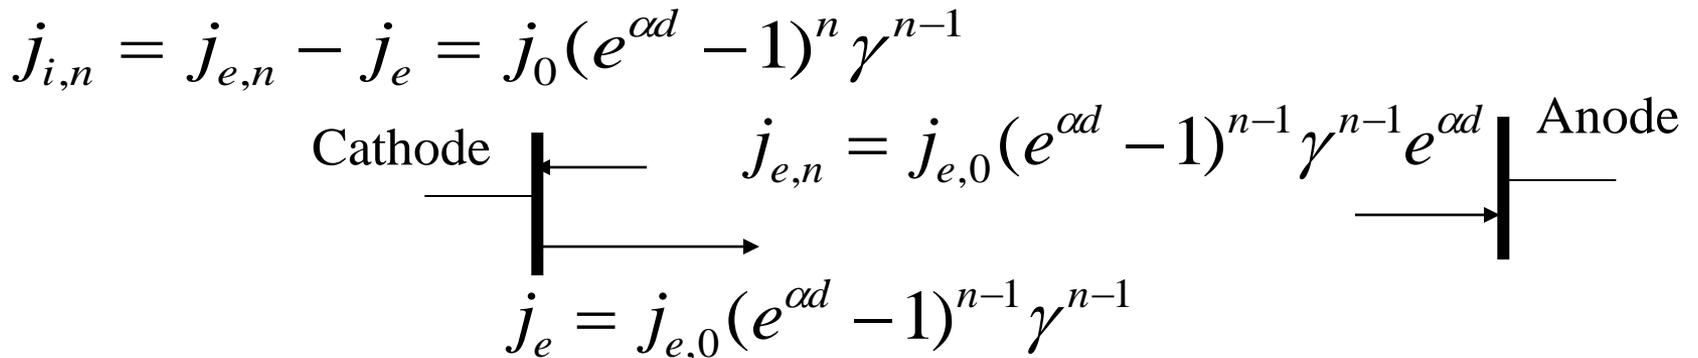

3rd generation

nth generation

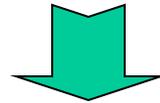

$$j_e = \sum_{i=1}^{\infty} j_{e,i} = j_0 e^{\alpha d} \sum_{i=1}^{\infty} \gamma^{i-1} (e^{\alpha d} - 1)^{i-1}$$

Geometric Series

If $\gamma(e^{\alpha d} - 1) < 1$

$$j_e = \frac{j_0 e^{\alpha d}}{1 - \gamma(e^{\alpha d} - 1)}$$

Secondary Emission Coefficient

$$j_e = \frac{j_0 e^{\int \alpha dx}}{1 - \Gamma(e^{\int \alpha dx} - 1) - (1 + \Gamma) \frac{\beta}{\alpha} e^{\int \alpha dx}}$$

First Townsend Coefficient:
(ionization by electron collision)

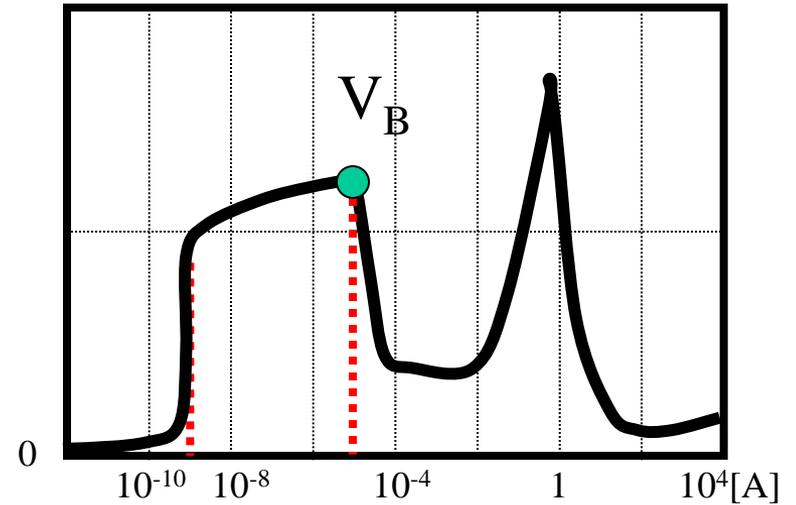

$$\alpha = C_1 \times p \times \exp\left(\frac{-C_2 \times p}{E}\right)$$

β is secondary Townsend coefficient: ionization rate by ion collisions

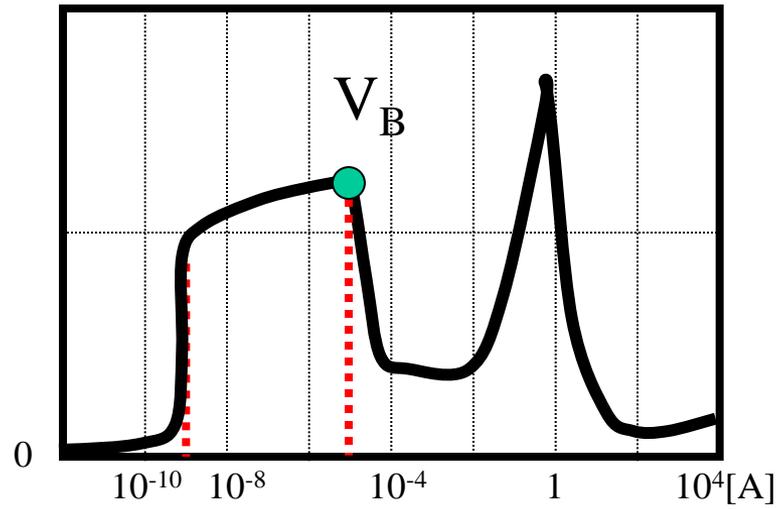

$$\Gamma = \gamma_i + \gamma_{photo} + \gamma_{meta} + \gamma_A$$

Breakdown Voltage

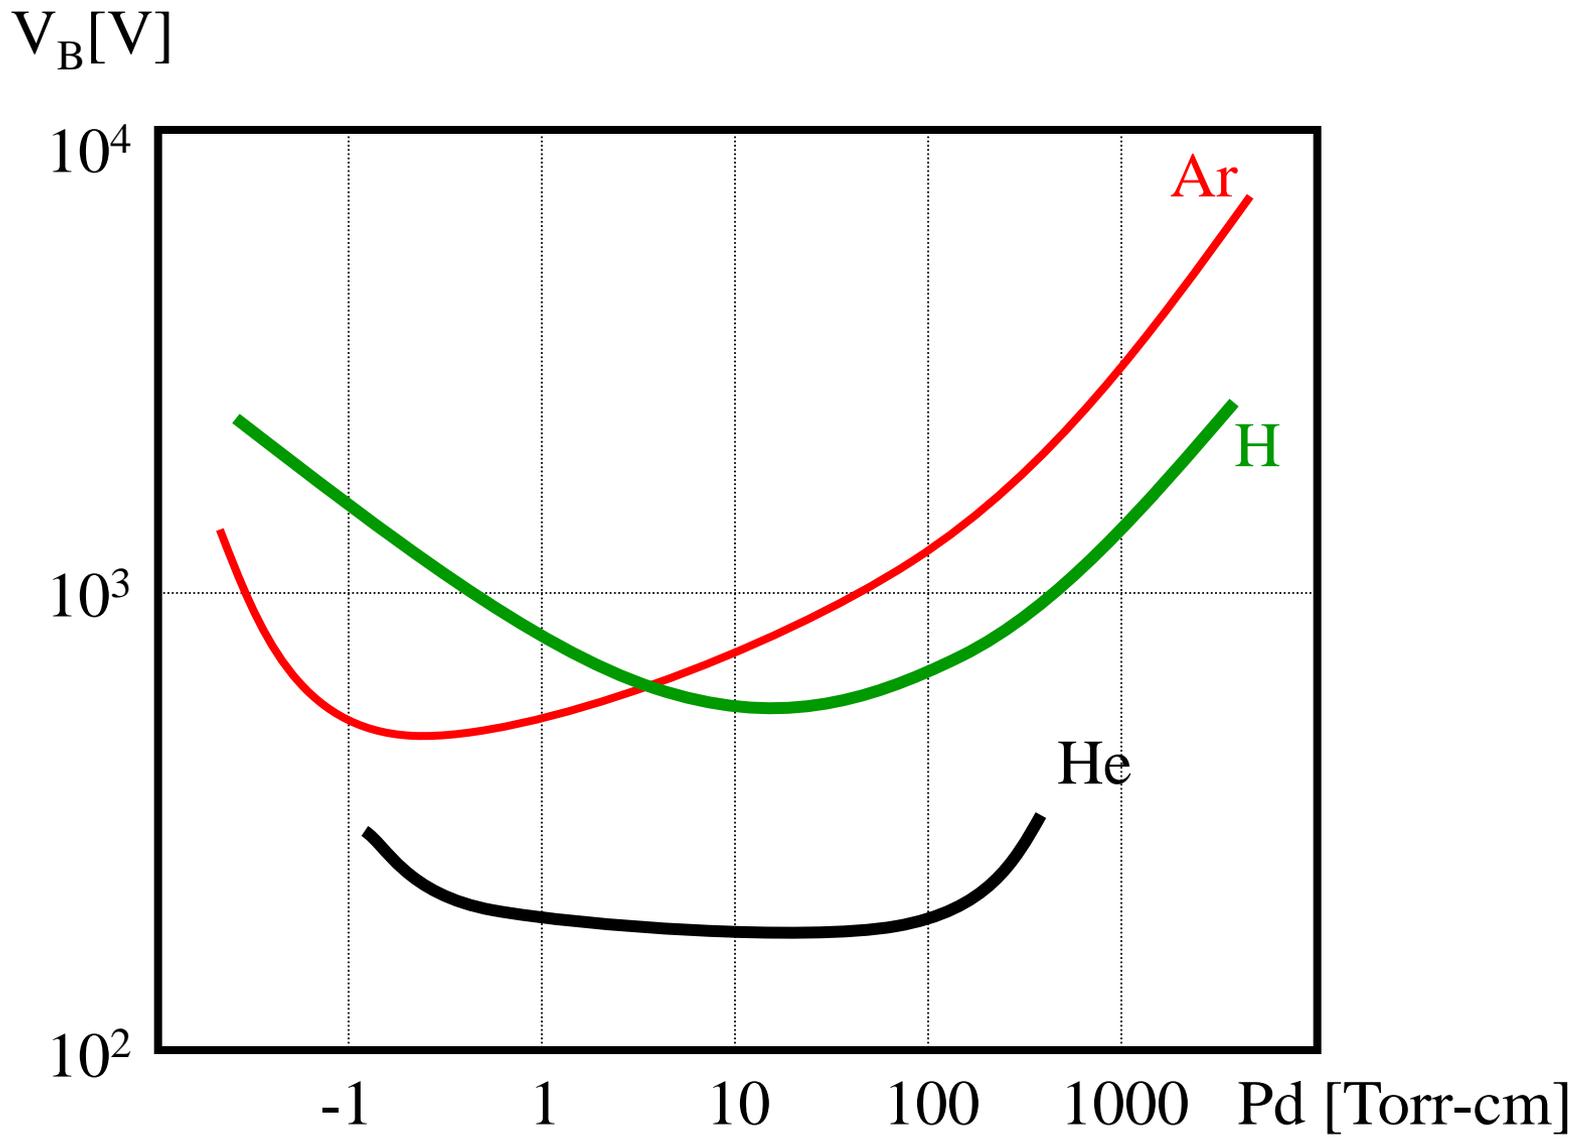

$$n_e = \frac{n_o e^{\alpha d}}{1 - \gamma(e^{\alpha d} - 1)}$$

$$\left\{ \begin{array}{l} \gamma(e^{\alpha d} - 1) = 1 \quad \text{Townsend breakdown criterion} \\ \alpha = C_1 \times p \times \exp\left(\frac{-C_2 \times p}{E}\right) \\ V = E \times d \end{array} \right.$$

$$V_B = \frac{C_2(pd)}{\underbrace{\ln(pd) + \ln C_1 - \ln\left(\ln\left(\frac{1}{\gamma} + 1\right)\right)}_{\text{Almost Constant}}}$$

Minimum Breakdown Condition

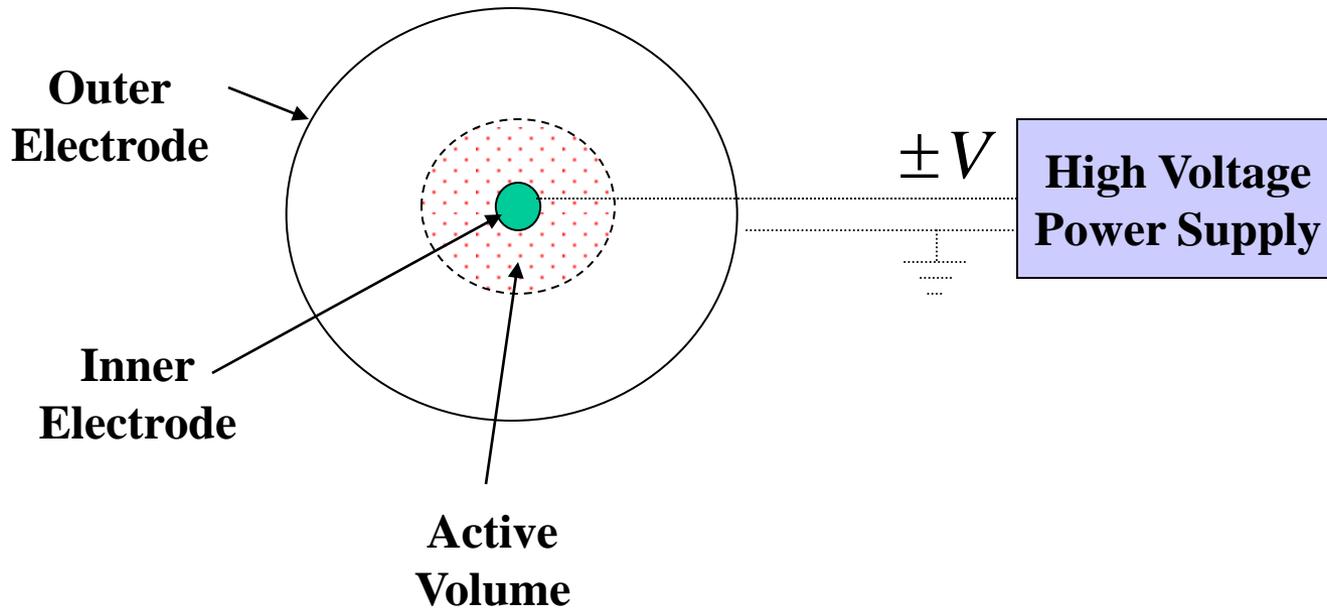

$$(pd)_{\min} = \frac{2.718}{C_1} \ln\left(1 + \frac{1}{\gamma}\right)$$

$$V_{b,\min} = 2.718 \frac{C_2}{C_1 \ln\left(1 + \frac{1}{\gamma}\right)}$$

Breakdown above ~100 Torr

$$V_b = 3000 d + 1.35 \text{ kV} \quad \text{for dry atmospheric air}$$
$$E_b \sim 30 \text{ kV/cm}$$

Corona Discharge

For dry Air for parallel electrodes:

$$V_B = 3000d + 1.35 \quad [\text{kV}]$$

$$E_B = \frac{V_B}{d} = 3000 + \frac{1.35}{d} \quad [\text{kV/m}]$$
